5th Given Name Surname
dept. name of organization (of Aff.)
name of organization (of Aff.)
name of organization (of Aff.)
City, Country
email address or ORCID

I. Background

In this section, provide a comprehensive overview of the problem or challenge your project addresses. Include the motivation behind selecting this topic, its relevance to the field, and any specific issues that your project seeks to resolve. Be sure to clearly define any terminology that is specific to your area of research. This section sets the stage for the entire report, so ensure it's clear and well-structured.

Our project seeks to identify a Deep Reinforcement Learning (DRL) model that is best suited to equip a car to merge onto and off of a highway. We were seeking to explore a topic in the realm of automated driving, and after some deliberation and exploration settled on specifically the act of merging onto and off of a highway. As drivers, many of us faced initial difficulty with this driving skill, so we thought it would be intriguing to explore how well DRL models would fair. We also considered it potentially challenging, such that it would be suitable for our Deep Learning class project. From our current research, we have yet to find anything that explores similar questions or tasks (TEAM NOTE: MAYBE WE SHOULD DO A LITTLE MORE RESEARCH TO FIND IF THERE ARE ANY EXISTING PAPERS ON MERGING??????).

Our tool to simulate the highway environment will be the "highway-env" python package. This package is a modification of the popular "gymnasium" python package that contains tools for building environments suitable for DRL or RL model training. "highway-env" contains many pre-designed driving environments (straight highway, racetrack, parking, etc.), and ours will be a modification of the "merge-v1" environment.

II. Related Studies

This section should demonstrate a thorough understanding of the existing work in your field. You are required to review at least five state-of-the-art models that are closely related to your project. For each paper, include the following: Model Name and Authors: Cite the paper and mention the model's creators. Methodology: Summarize the key techniques or algorithms used in the model. Focus on how these models approach the problem at hand. Performance: Provide a comparison of each model's performance based on standard benchmarks (e.g., accuracy, precision, recall, etc.) and briefly mention any notable strengths or weaknesses. The discussion should not only summarize but also critically analyze how these existing models have informed your own project. Highlight how your approach builds upon or deviates from these studies

The first model we reviewed was PPO+ [1], created by M. Kallel, J. Holgado-Alvarez, S. Tosatto, and C. D'Eramo. PPO+ is an implementation of Proximal Policy Optimization (PPO) [2] that improves some of the shortcomings of PPO, taking inspiration from off-policy actor-critic models such as SAC [3]. PPO is a popular on-policy models created by J. Schulman, F. Wolski, P. Dhariwal, A. Radford, and O. Klimov. PPO utilizes actor and critic networks to find the optimal policy directly, first by using the current policy to iterate over some number of environment steps, using the critic network to compute the advantage for each action, and to compute the policy losses through mini batches of the samples collected in the previous environment to update the actor and critic networks. Specifically, PPO+ aims to: 1) improve the accuracy of the critic network of PPO, 2) bound the action spaces, and 3) provide entropy regularization. To address the critic accuracy, PPO+ implements a replay buffer to store past policy information to supplement the training of the critic network (instead of just using current policy information). This makes critic training off-policy, but maintains the core requirement of the actor network being on-policy. For bounding the action spaces,

PPO+ utilizes a hyperbolic tangent when computing the log probabibilities of the policies while applying corrections for when the action value diverges at ± 1. For performance, PPO+ in the MuJoCo dataset performs above average in total policy return compared with PPO [2], SAC [3], and TRPO [4], and laregely outperforms those same models in the DOG environment of the Deepmind Control Suite. And to address entropy regularization, PPO+ adds an entropy term in the computation of the avantage. PPO+'s strengths include general strengths for on-policy models, such as stable learning and safer exploration, and improvements to PPO (the dominant on-policy model) such as a more accurate critic, bounding the policy distribution and maximizing entropy exploration. PPO+, suffers from similar weaknesses as to other on-policy models such as poor sample efficiency.

TODO - ppo+ do we have to cite mujoco - https://ieeexplore.ieee.org/abstract/document/6386109
deepmind control suite - https://arxiv.org/abs/1801.00690

TODO (after 5 models): highlight how our own approachs builds/deviates from these studies

TODO: DOUBLE CHECK IEEE CITATION FORMAT
